Documentation Lab HCI

Name: Nadya Angelie Lislie

NIM: 2702321680

Instruction:

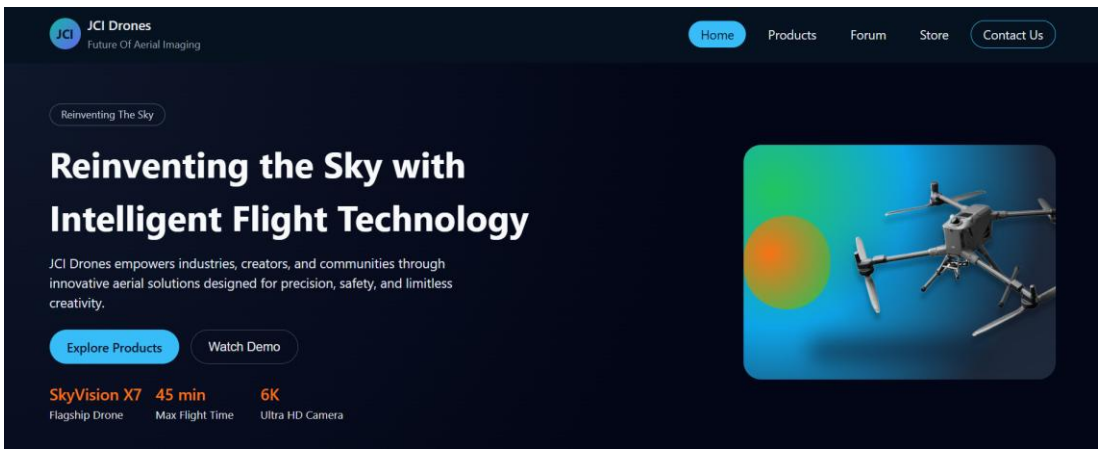

File yang harus dikumpulkan adalah keseluruhan jawaban beserta dengan aset yang digunakan (gambar, audio, video, dll) dan dokumentasi proyek yang berisikan link referensi aset dan penjelasan mengenai aplikasi yang dibuat (**terlampir bersama dengan soal**).

The fulfilment of requirements from JCI are described below:

1. JCI wants you to design the **website prototype** of all five pages before making the HTML files. The website prototype will be created using Figma. Ensure the website prototype that you created is **intentionally different** from the website that you will make later, even if the themes are the same. Each page will contain header, navigation, content, and footer as its structure. Consider the color, layout, and consistency when designing the prototype.
   = Done

2. JCI wants you to build the **website attractive**, **appealing**, **fully functional**, and make sure the website is **responsive**. The website should be accessible using a mobile phone in a perfect way. To achieve that, use **5 kinds of CSS property** and **JavaScript**. Use **meta** viewport tag and **media screen rule** that will be applied if the screen is **below 600px** and/or **768px** screen width.
   = Done for the website made using code (also shown below)

   - Big Screen:

Advexure

Phone: (855) 625-2055
Email: contact@advexure.com
Location: 2288 Westwood Blvd, Los Angeles, CA 90064

Explanation:

These screenshots show how my JCI Drones website looks on large screens and on small screens. On the big screen views, you can see all four main pages:

- Home: wide hero banner, product highlight, video, awards, expertise cards, and CTA.
- Products: grid of product cards with images, price, and a type filter at the top.
- Forum: sidebar with “Popular Tags” on the left and discussion cards on the right.
- Store & Contact Us: store tabs for “Official Online Stores / Retail Stores”, and a two-column contact layout (info panel + form).

These are captured on a wide canvas to show that everything sits inside a centered .container with max-width, so on desktop the content is not stretched too

much and stays neat. On the small screen views, the same pages are shown but with a different layout:

- The top navigation turns into a hamburger menu. JavaScript toggles a CSS class on the <nav> so the links slide down under the header.
- Grids such as the product cards, forum layout, store cards, and contact form switch from multi-column layout to single column using media queries (@media(max-width: 768px) and @media(max-width: 600px)).
- The filter dropdown on the Products page stays full width and easy to tap, and the cards stack vertically so users can scroll.
- On the Contact page, the info box and the form that were side by side on desktop are stacked on top of each other on mobile for better readability.

To make it responsive I did a few key things:

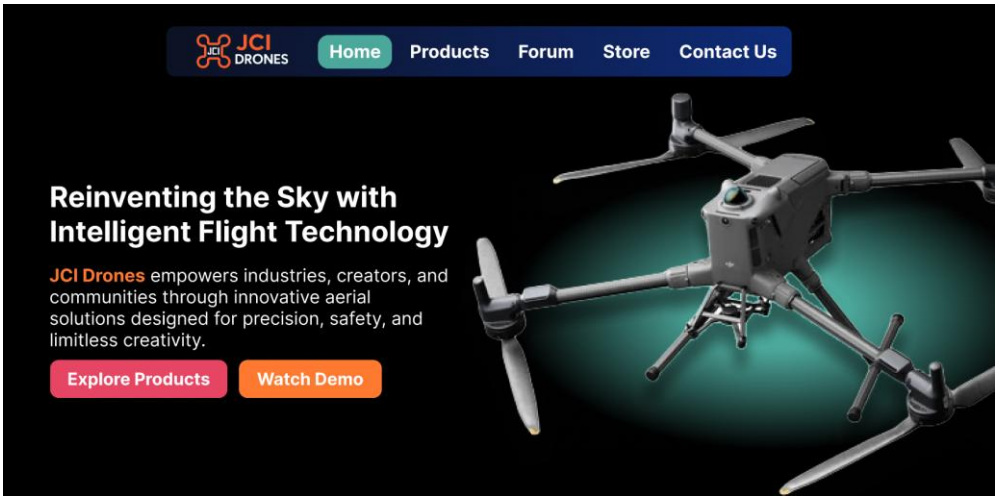

- Added the meta viewport taf
- Used flexbox and CSS grid for layout (display: flex;, display: grid;) with percentages and fr units instead of fixed pixel widths.
- Wrapped all content in a .container with max-width and side padding so it looks good on large screens but still shrinks nicely on small ones.
- Wrote media queries:
  - At max-width: 768px I change grids from 3–4 columns to 1–2 columns, adjust hero layout, and tweak the footer and store layout.
  - At max-width: 600px I switch the header to mobile mode (hamburger nav) and stack almost everything vertically.
- Made images and videos responsive (width: 100%; height: auto; or object-fit: cover;) so they resize with their containers without breaking the layout.

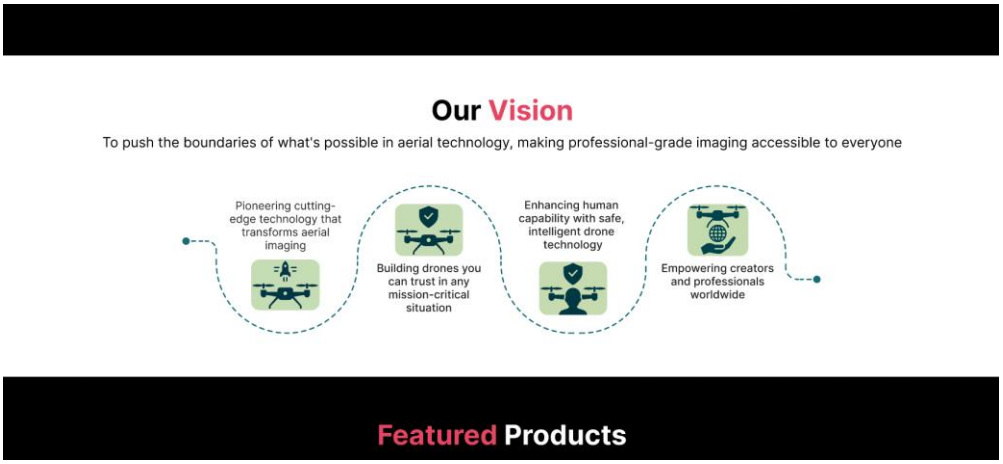

3. The website consists of **five main pages**. They are **Home Page**, **Products Page**, **Forum Page**, **Store Page**, and **Contact Us Page**. Below are the **requirements** for each page:

- **Home Page**

  This page shows the banner that displays the identity of the company. It should at least consist of the company vision (through banner, slogan, etc.), example photo/video from JCI products, the JCI's innovation awards, and JCI's field of expertise.

  a. Company vision (through banner, slogan, etc.)
     - **Figma**

- **Website Code**

Explanation:

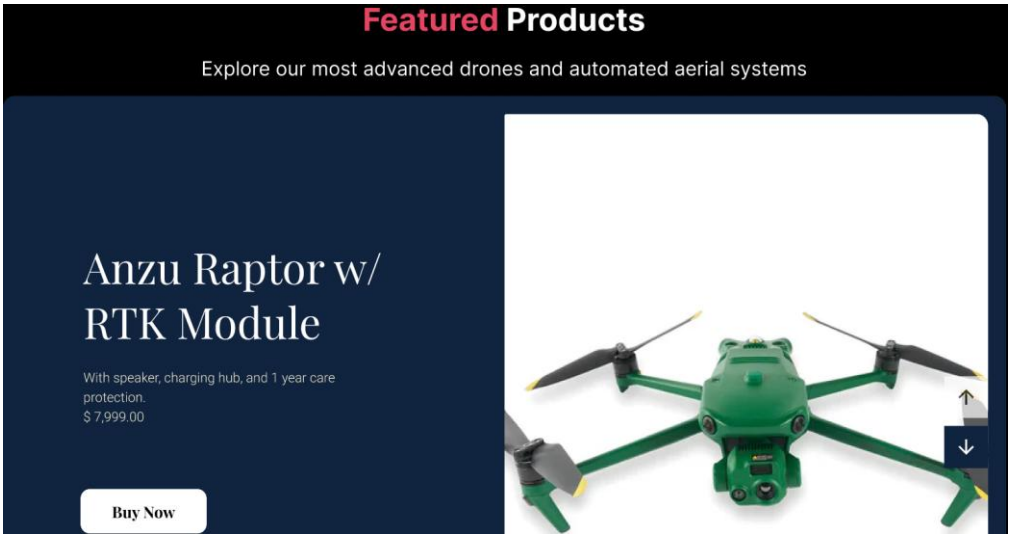

In the Figma design, the hero section is styled as a strong visual introduction. It uses a dark gradient background, a bold headline, short supporting text, and two action buttons. A drone image sits on the right side, creating a clean split layout. The company vision section in Figma is also structured (a centered title, a short sentence describing the mission, and four vision items arranged in one row with light icons and connecting dotted lines.)

When I built the website using HTML, CSS, and JavaScript, I followed the same layout and visual hierarchy. The hero section matches the Figma look closely same text placement, buttons, and drone image position. The navbar is also recreated with hover effects and becomes a mobile menu when the screen width gets smaller. For the vision section, I kept the same four item structure and centered layout from Figma, using CSS Grid to control spacing. I also added responsive styling, so the boxes rearrange into stacked rows on mobile, making the content readable on all screen sizes.

Both the Figma design and the coded website show the same structure and message, including the full company vision, but the coded version adds responsiveness and real interaction to make the layout work across desktop and mobile.

b. Example photo/video from JCI products

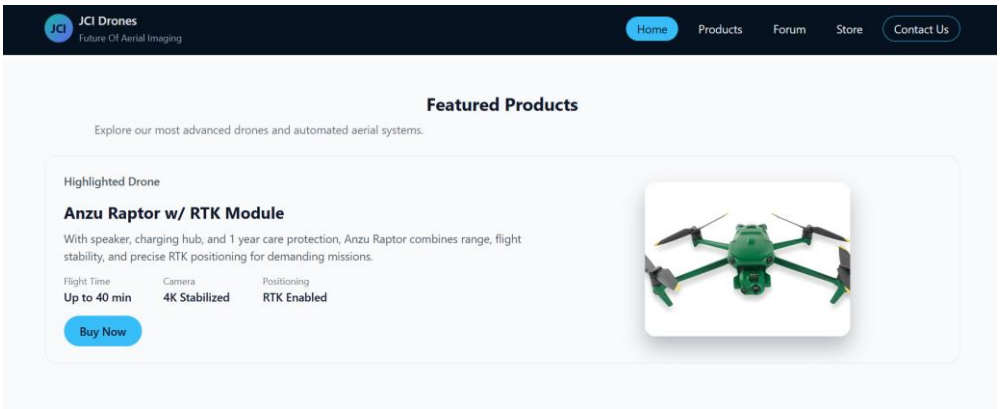

- **Figma**

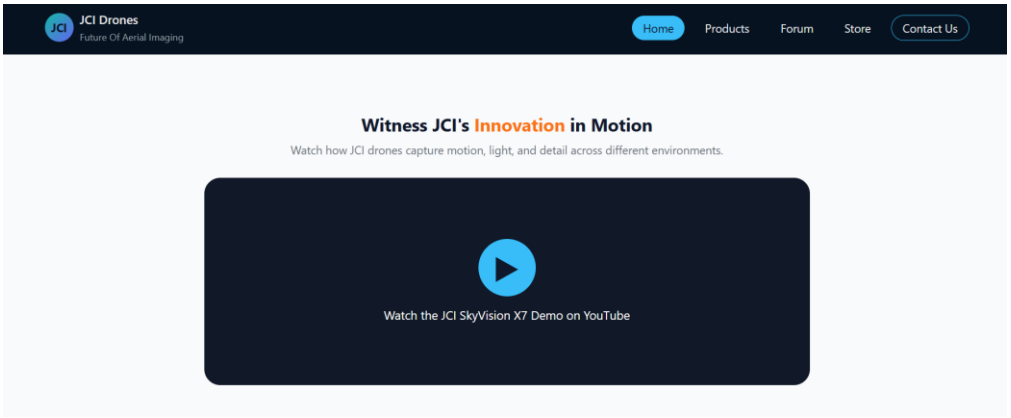

- **Website Code**

Explanation:

In Figma, I designed the Featured Products section using a carousel layout. This shows multiple product cards (3) can slide up anddown. The carousel helps show more than one drone model in a compact space, and it gives a more dynamic feel in the design stage. However, when building the actual website using code, I changed the approach. Instead of a full carousel, the coded version highlights one featured drone at a time. This makes the layout simpler, loads faster, and works better on different screen sizes.

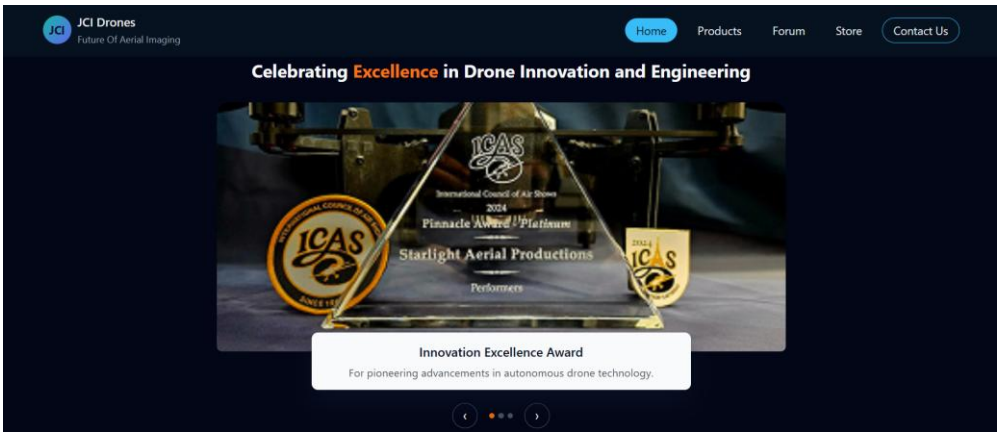

For the video section, Figma cannot play actual videos unless I subscribe to upload a video file. Because of that limitation, the Figma mockup only shows a static frame, acting as a placeholder to show where the video would go. But in the coded website, the video is fully functional and plays directly from YouTube, which means users can watch the real drone demo without downloading anything.

c. JCI's innovation awards

- **Figma**

- **Website Code**

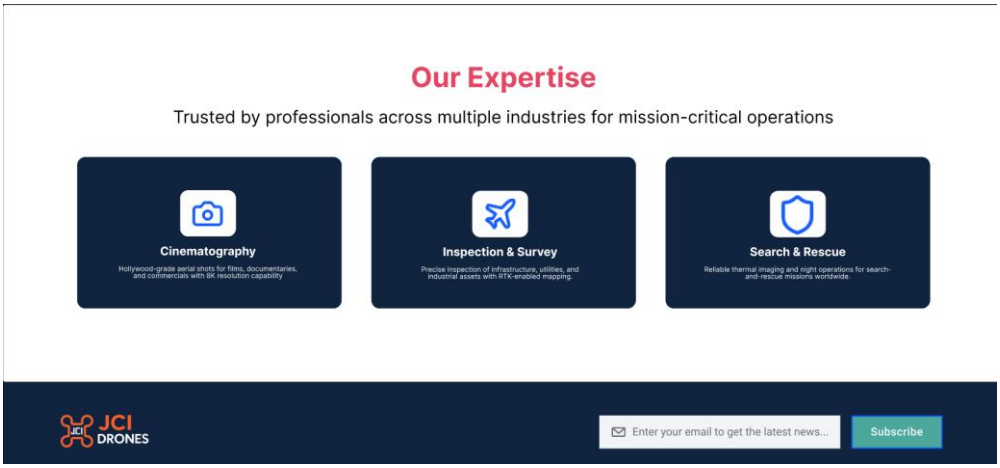

Explanation:

In the Figma design, the awards section shows three award cards displayed side-by-side. It is a static layout, meaning all awards are visible at the same time and there is no carousel interaction. Figma can display the visual concept easily, but it does not include dynamic movement or sliding effects unless using advanced prototyping.

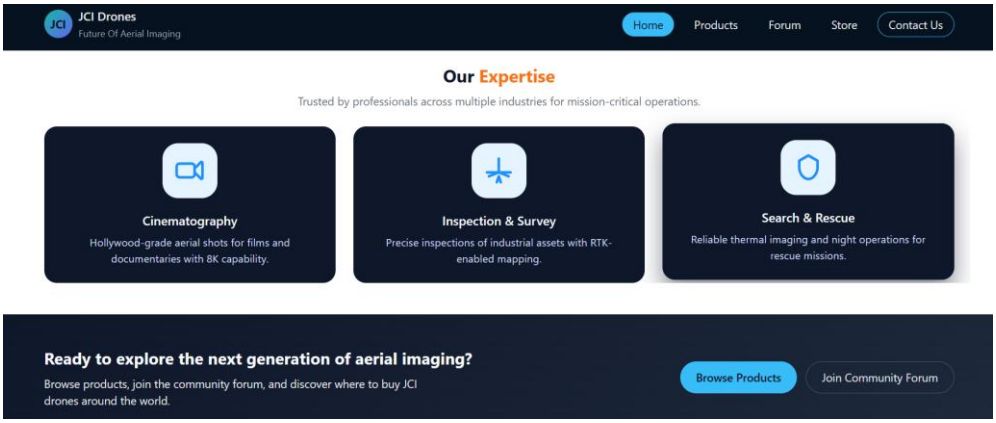

In the website version, I improved this section by turning it into a fully functional carousel. Only one award is shown at a time, and the user can switch between awards using the navigation arrows or dots. This makes the section more interactive, saves space, and feels more modern, especially for smaller screens.

d. JCI's field of expertise

- **Figma**

- **Website Code**

Explanation:

In the Figma design, the expertise section is displayed as three static cards showing Cinematography, Inspection and Survey, and Search and Rescue. It focuses mainly on the visual layout, icon placement, and overall structure. Everything is fixed because Figma is meant for design preview.

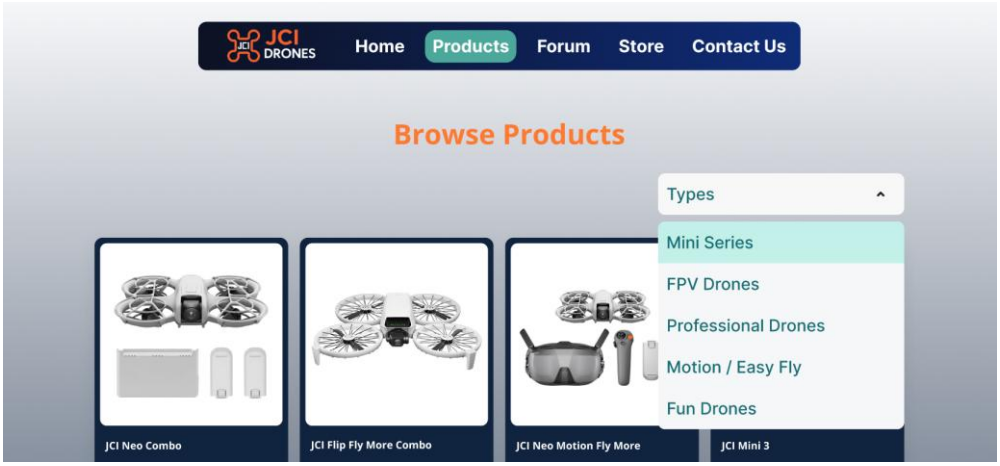

In the website version, the same three expertise cards are recreated with responsive styling. The layout adjusts smoothly for different screen sizes, and spacing, shadows, and colors are refined to match the final website theme. The coded version also adds a CTA section underneath, making the design more engaging and functional.

- **Products Page**

  This page shows list of **drone types** that are easy for people to **open specific drone** from a certain type. You should provide at least **top 5 drone highlights** that consist of **drone name**, **short description**, and a **button** that redirects user to **Store Page**.

  a. List of drone types

  - Figma

- Website Code

Explanation:

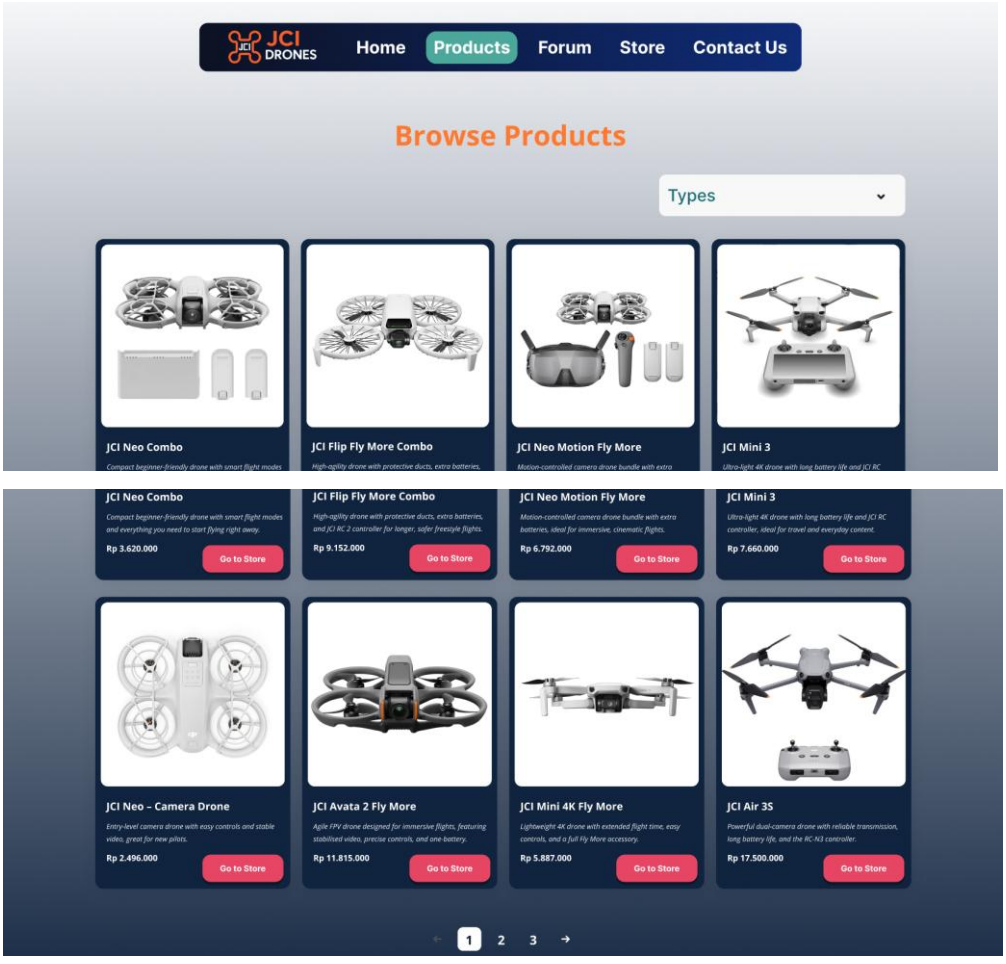

In the Figma design, I grouped the drones into several categories such as Mini Series, FPV Drones, Professional Drones, Motion/Easy Fly, and Fun Drones. The

dropdown in Figma is only a visual representation, but it shows how the products should be organized. The prototype is also clicable and it will acces sthe page accordingly.

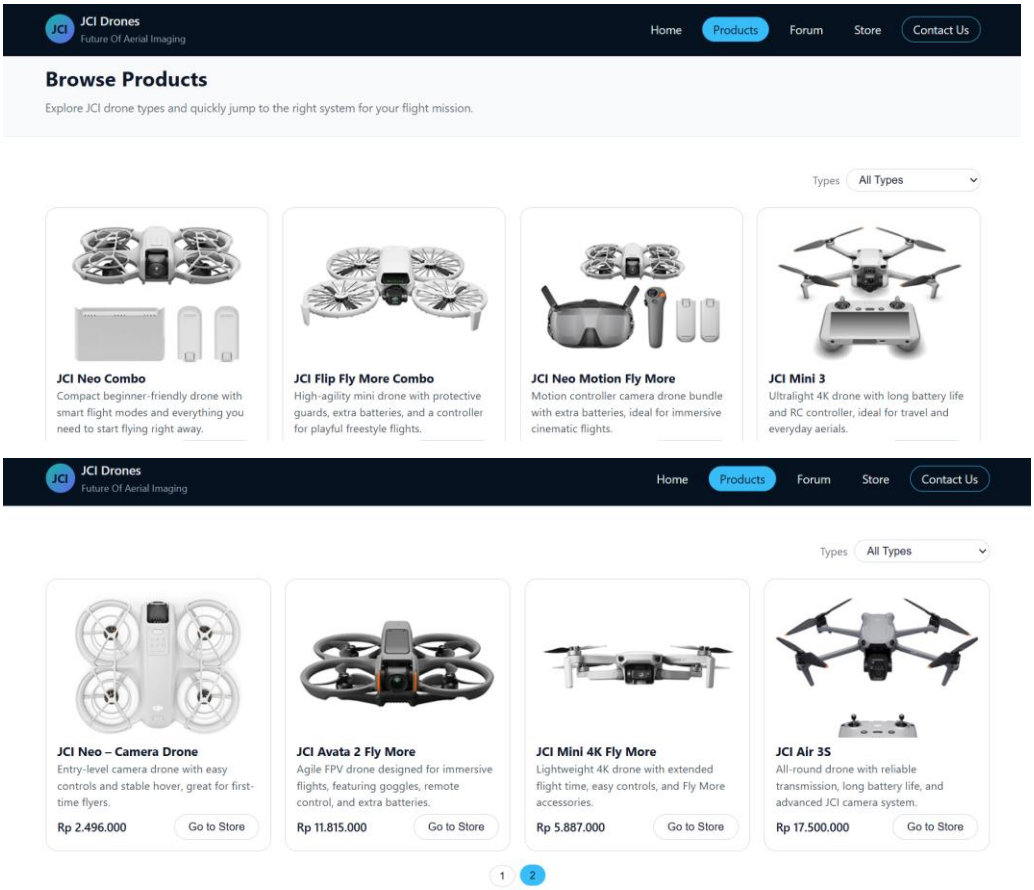

In the website version, this idea becomes fully functional. The dropdown menu is connected to JavaScript, so when a user selects a type (for example, “FPV Drones”), the page automatically shows only the drones that belong to that category and hides the rest. This makes browsing easier and more user-friendly.

b. Top 5 drone highlights consist of drone name, short description, and a button that redirects user to Store Page

- Figma

- Website Code

Explanation:

In the Figma design, each drone highlight is presented with three main elements (Drone name, a short description, a button that redirects the user to the Store page) This same structure is implemented in the coded website, making the user experience consistent across both platforms. Each product card clearly shows the important information at a glance and provides a direct call-to-action button ("Go to Store") so users can quickly continue to the purchasing page.

Both the Figma and the coded version also include pagination. This allows the list of drones to be split into multiple pages instead of stacking everything in one long layout. Pagination helps keep the interface clean and prevents overwhelming the user with too many items at once. In the coded version, the pagination is fully functional, clicking page numbers changes the displayed drone list dynamically.

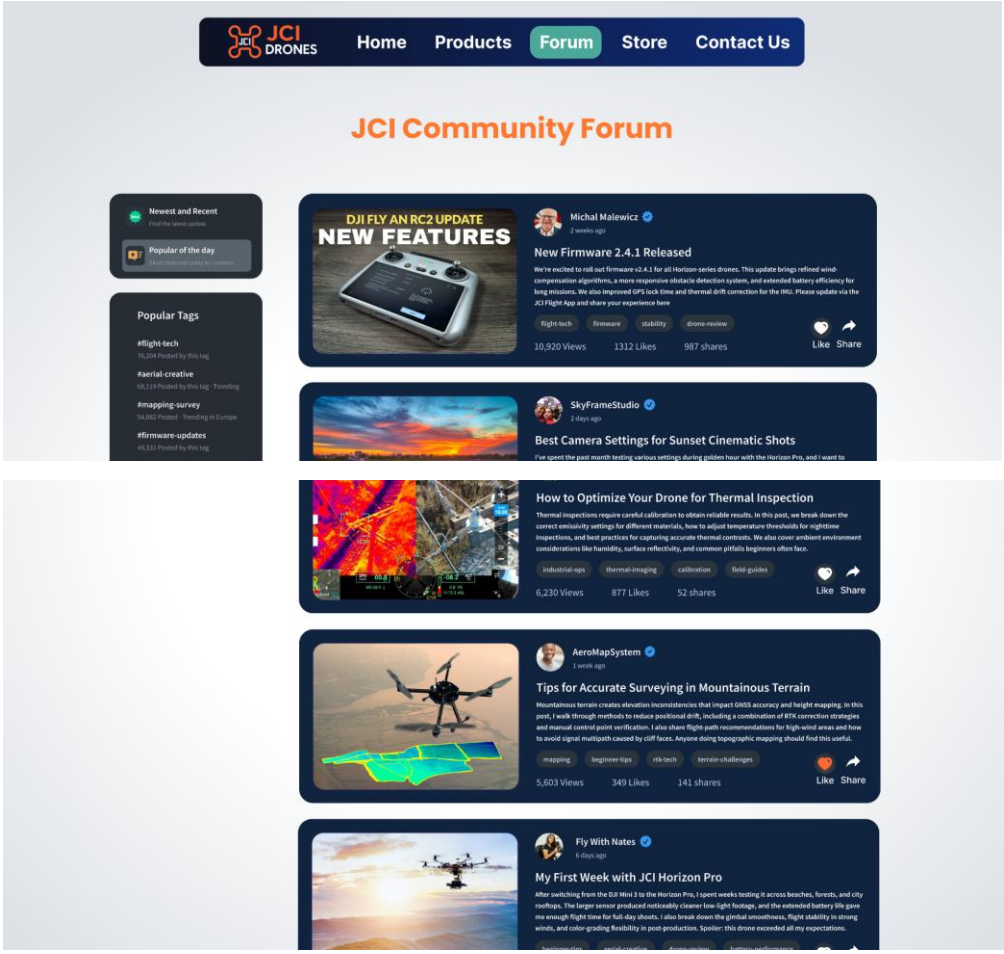

- **Forum Page**

This page provides a display of all forum posts from company representatives and all verified users. It should display a list of forum posts that consists of **creator username**,

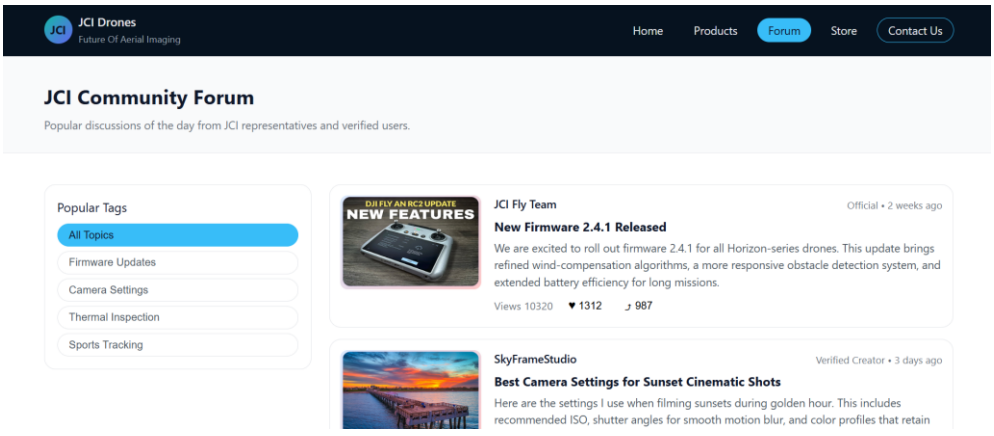

forum title, **forum description**, and a section of **view count**, **likes**, and **share count**. Users should also be able to find posts based on the **hot categories**.

a. Display of all forum posts from company representatives and all verified users

- Figma

- Website Code

Explanation:

In the Figma design, the forum page shows a full list of posts created by verified users and official JCI representatives. Each post includes a thumbnail, title, short description, and engagement info such as views, likes, and shares. The accounts also display a verification badge, making it easy for users to identify trusted contributors.

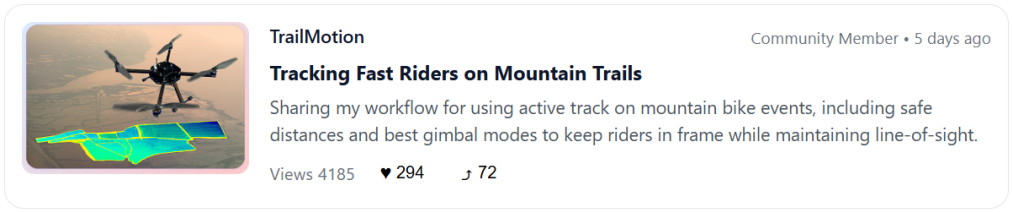

In the coded website, the same structure is implemented. The page lists forum posts with their images, titles, and short content previews. Verified accounts are marked with a title instead of a badge. The layout is cleaner and more spaced in the coded version, but it still follows the same idea from Figma: show a feed of posts from trusted users and JCI representatives.

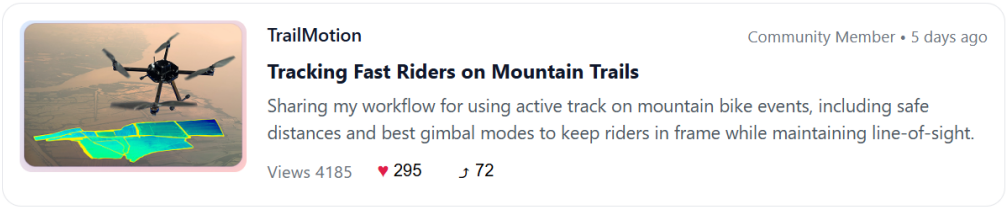

b. Forum posts that consists of creator username, forum title, forum description, and a section of view count, likes, and share count.

- Figma

- Website Code

Explanation:

In the Figma design, each forum post shows the creator's username, the post title, a short description, and the view, like, and share counts. The like button is

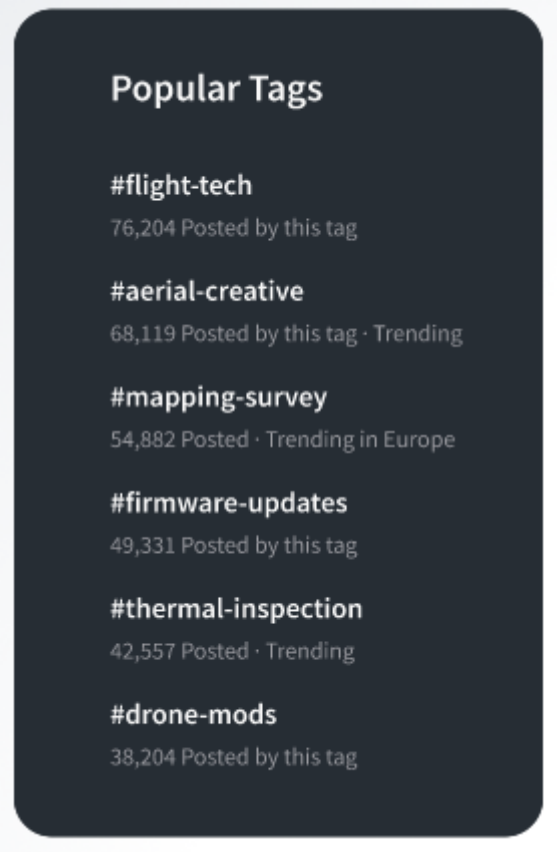

also displayed, but it is only a visual mock-up. You can click the like button in Figma for demonstration, but the number besides it never changes because Figma is not interactive, it only shows the design.

In the coded website, the same structure is fully functional. The like button can be clicked just like in Figma, but now the number actually updates. When a user likes a post, the count increases, and when they unlike it, the count decreases. This adds real interaction that Figma cannot provide.

So, both versions allow clicking the like button, but only the coded website reflects real changes in the like count, making the forum behave like a real platform.

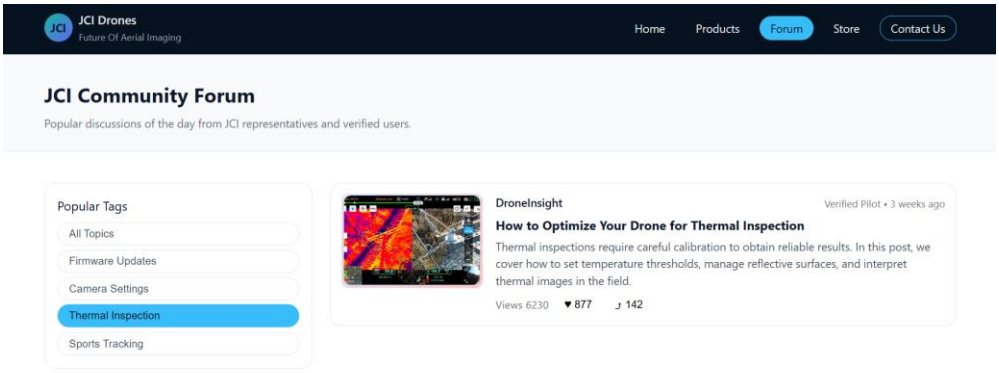

c. Find posts based on the hot categories

- Figma

- Website Code

Explanation:

In the Figma design, the "Popular Tags" section displays a list of trending categories such as flight-tech, aerial-creative, and thermal-inspection. These tags act as visual filters that help users understand what topics are currently active in the community. Since Figma is only a prototype, the tags are static and do not actually filter the posts. However, the top two does direct to the actual filter (I made it manually)

In the coded website, the same tag system is implemented but made functional. Users can click on any tag such as Firmware Updates or Thermal Inspection and the website immediately filters the forum posts to show only the entries that match that category. This creates a real interactive experience.

- **Store Page**

This page provides **information** about where users can buy JCI products. Users should also be highlighted that they can buy their product through **JCI official app** in Google Play and App Store and **JCI official store** in various **e-commerce platforms**.

a. Information about where users can buy JCI products. Can buy their product through JCI official app in Google Play and App Store.

- Figma

- Website Code

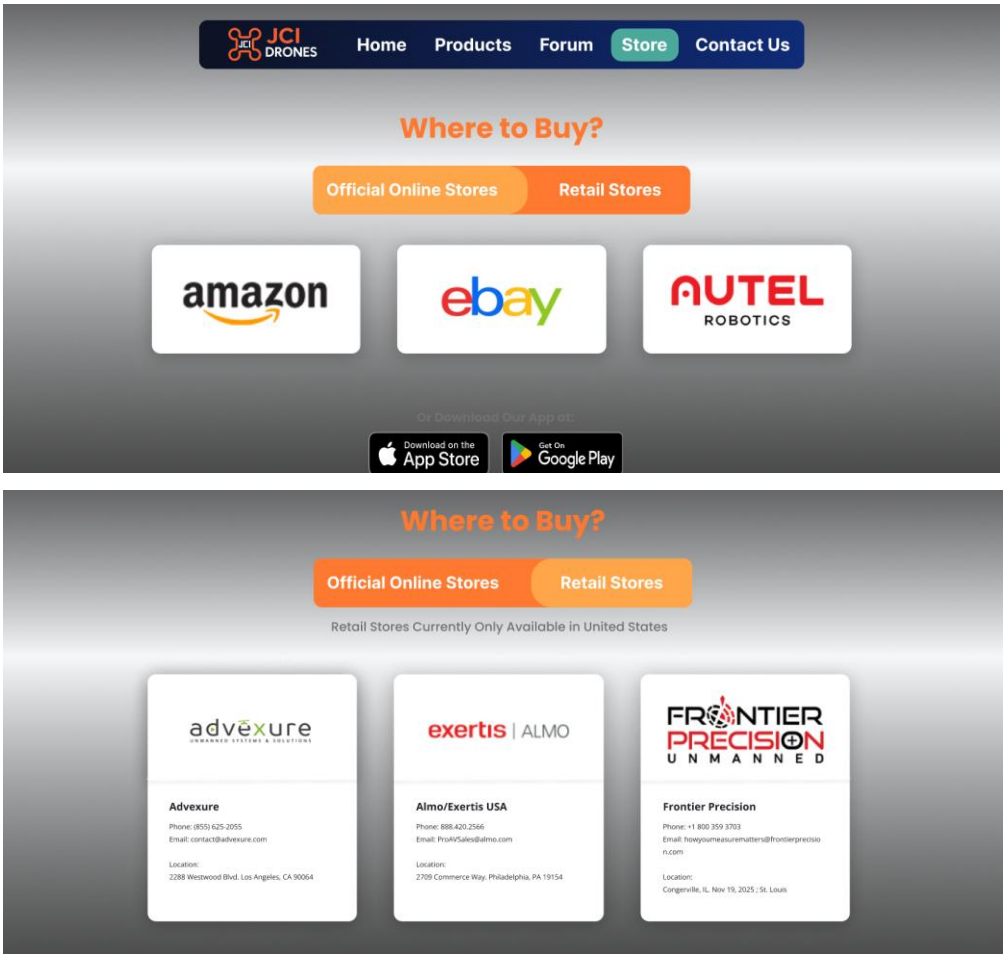

Explanation:

In the Figma design, the section simply shows the app-store badges (App Store and Google Play) as static images. These visuals communicate that users can download the official JCI app to buy and manage their products, but there is no real interaction since Figma only represents the layout.

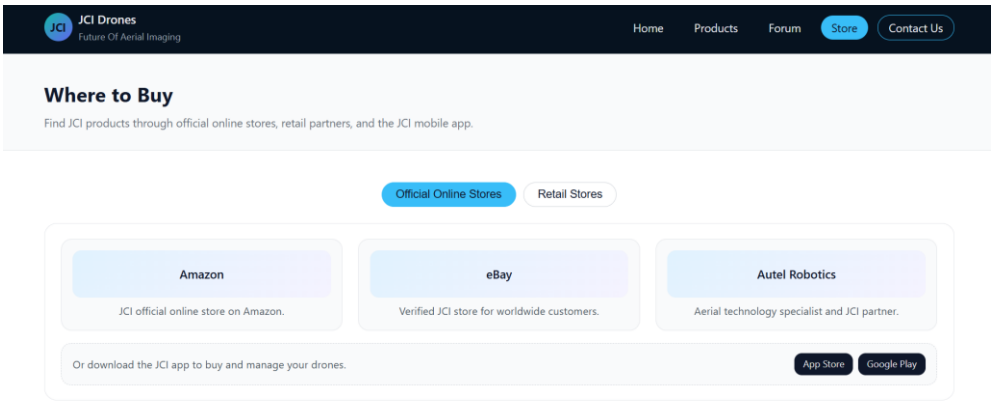

In the coded website, the same idea is implemented but made functional and lightweight. The App Store and Google Play buttons are clickable, making it possible for users to be redirected to the actual platforms. The website version keeps the interface clean while still delivering the same information as the Figma mockup

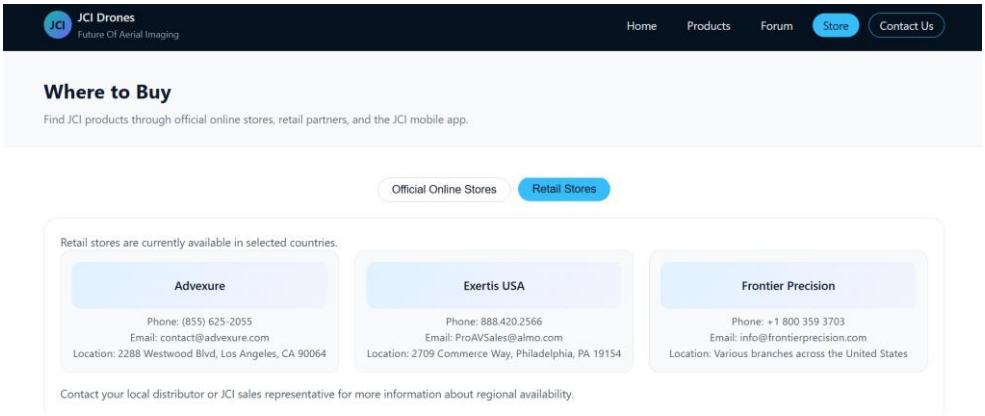

b. JCI official store in various e-commerce platforms

- Figma

- Website Code

Explanation:

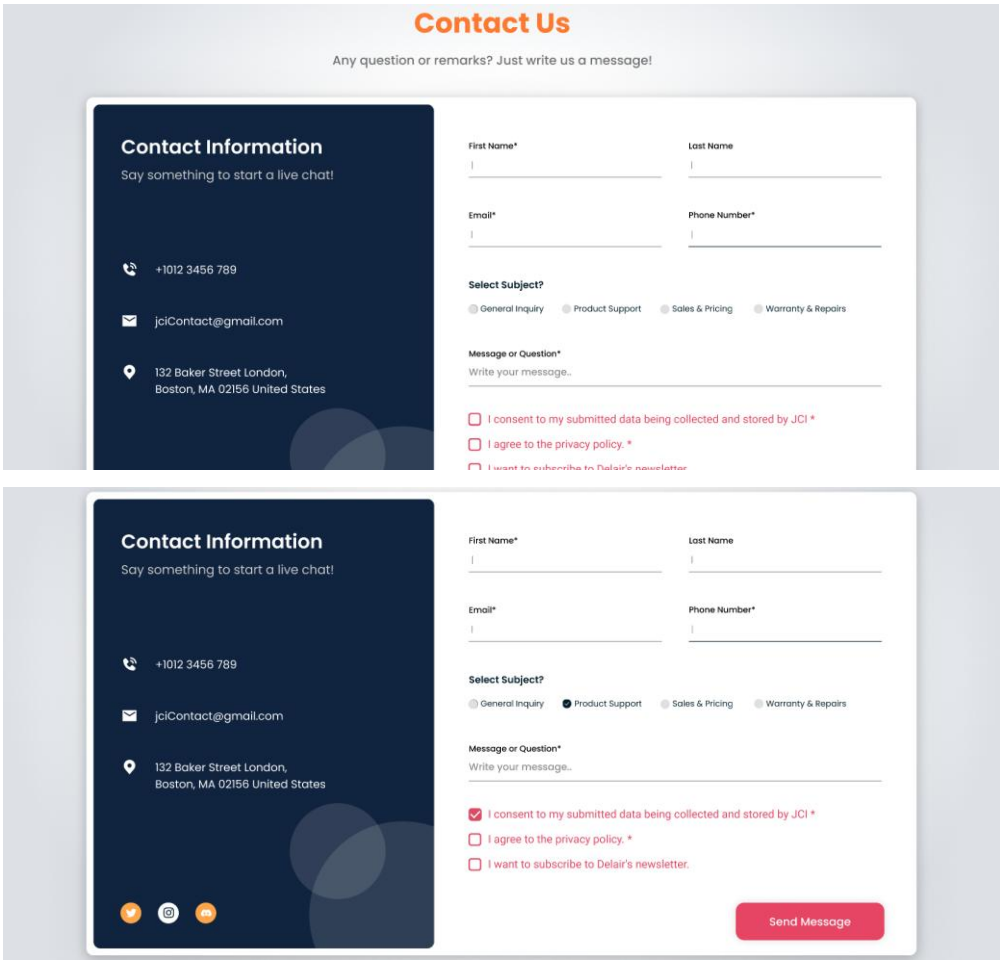

Both Figma and the coded website display three well known online platforms (Amazon, eBay, Autel Robotics) as the online stores. It shows that these are the official online stores where customers can buy JCI products. This clicable to the official website.

- **Contact Us Page**

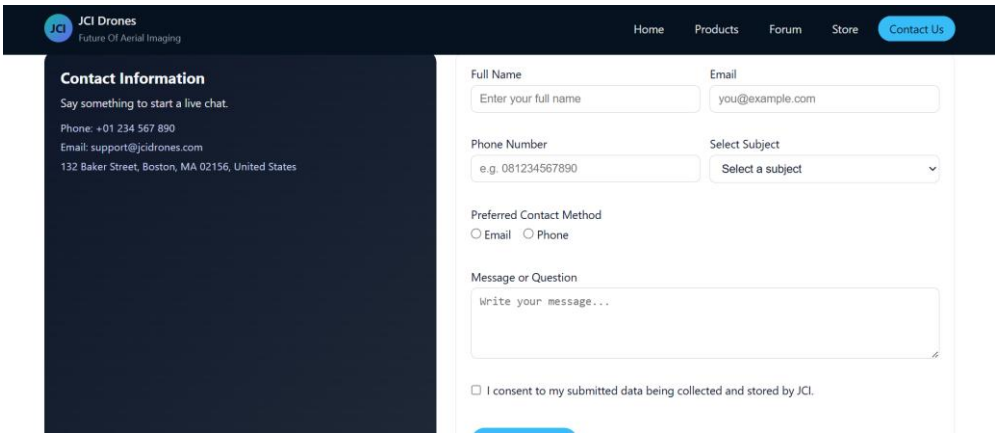

This page provides users with a way to contact JCI through **support form**. Users need to provide some personal information, such as **name**, **phone number**, **email**, etc. Users also need to provide the **message** that will be received by JCI contact center. Last thing, users should **agree** to JCI **term of service** of how they handle users' data. Also, you are asked to create **five kinds of form components** and **five kinds of validation**. For validation, you must create it using **JavaScript** and **don't use regular expressions**.

a. Users need to provide some personal information, such as name, phone number, email, etc. Users also need to provide the message that will be received by JCI contact center. Users should agree to JCI term of service of how they handle users' data.

   - Figma

- Website Code

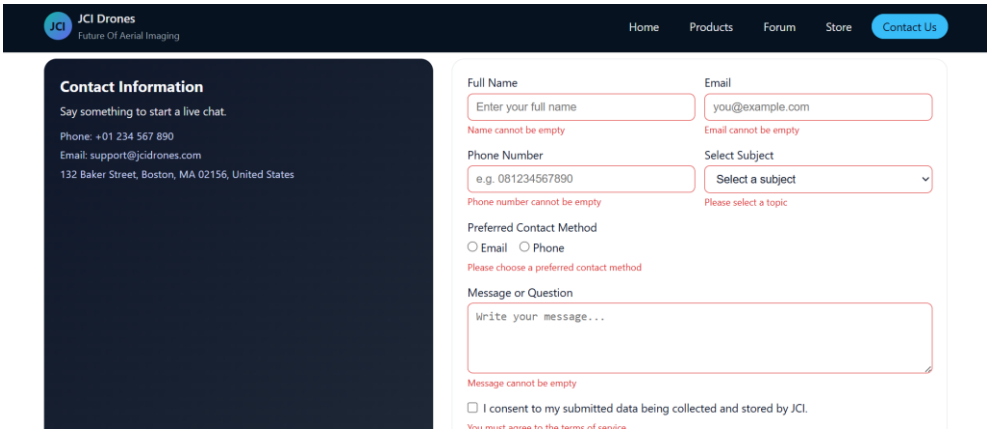

Explanation:

In the Figma design, the Contact Us page shows all the required fields such as name, email, phone number, subject, and message. It also includes a checkbox area where users can agree to the terms of service. The layout is clean and organized, showing both the contact info panel and the form side byside. However, Figma is

only a design tool, so the form does not perform any real validation. The checkboxes can be clicked visually, but Figma does not check if the fields are empty or wrong, and it cannot show error messages. It only represents how the final design should look. For the coded website explanation, I will explain below.

b. Validation (code) no REGEXP

- Website Code

Explanation:

In the coded website, the same structure from Figma is implemented but made fully functional. Every field is validated using JavaScript. The form checks:

- if the name is filled correctly
- if the email has valid format
- if the phone number contains only digits
- if the user has selected a subject
- if a message is written
- if the terms of service checkbox is checked

If any requirement is not fulfilled, the website shows error messages and highlights the incorrect fields. The checkboxes also work properly and are needed before submitting. This makes the form behave like a real contact system, unlike the static version in Figma. Also, I did not use any REGEXP (regular expressions) to validate inputs. Instead, the validation is done using basic JavaScript logic and simple character checks. As instructed

Are the guidelines being followed?

a. Design your website by observing the principles of **human and computer interaction**. Set up your site as **creative** as possible but still strive for **consistency**. = Yes

b. The **website prototype** must be designed using **Figma** and make sure to create some **features**, such as color and text style, effect, component, variant or interactive component, and navigation. = Yes

c. Consider the **color**, **font**, **size**, and **layout** that you use to design the prototype and website. = Yes

d. All pages mentioned in the requirement should be created **based on your template design**. = Yes

e. Use only **external CSS**. Internal or inline CSS will not be marked. = Yes

f. Use **CSS box positioning** to design your web structure**,** do not use table for the layout. = Yes

g. Consider the **language** you use, including spelling and grammar, feel free to choose either Bahasa or English, but you cannot have both at the same time. = English

h. Make your website **responsive** so it can deliver in any size, particularly for **desktops**, **tablets,** and **mobile devices**. = Yes the website using code

i. Organize your files with subdirectories. = Yes (The assets are in img folder inside the HCI Lab Code folder)

j. Include references (link from a website, book, etc) that you use in creating the website.
